ABSTRACT

Long-form customer reviews across e-commerce platforms like Amazon contain valuable feedback on mobile gadgets, but manually processing them is time-consuming and inefficient. This project presents an automated **Sentiment Analysis system** built using a **Lexicon-based Natural Language Processing (NLP)** model, specifically **VADER (Valence Aware Dictionary and sEntiment Reasoner)**. The system processes a dataset of mobile gadget reviews by integrating product information and review text. It then applies the VADER algorithm to classify the sentiment of each review as **Positive, Negative, or Neutral**. The core output is a comparative analysis of different mobile brands (Samsung, Motorola, Nokia) based on their average customer satisfaction scores. The results confirm that NLP-based sentiment analysis can significantly enhance market understanding, allowing companies to quickly identify consumer pain points and product strengths.

Introduction

Project Background & Context

The contemporary digital marketplace is characterized by the exponential growth of e-commerce, where customers generate massive volumes of data in the form of product reviews. While this consumer feedback is an invaluable source of market intelligence for manufacturers and retailers, the sheer scale and unstructured format of this text-based data make its analysis by conventional, manual methods unfeasible. This project is designed to address this precise challenge by utilizing a Machine Learning-driven approach to automatically process and interpret customer opinions related to mobile devices. The fundamental goal is to systematically convert raw, free-form text into structured, quantifiable sentiment scores.

Problem Formulation

The core problem addressed by this project is the efficient conversion of vast, unstructured review data into actionable market intelligence. This challenge primarily involves two distinct hurdles: **First**, the necessity of reliably merging heterogeneous datasets, specifically linking the raw product review text with the corresponding item metadata. **Second**, the subsequent requirement to quickly and accurately classify the emotional tone, or sentiment, present in the review text for thousands of entries. The final classification system must be sufficiently rapid and effective to deliver an easily interpretable, quantitative metric of customer satisfaction for comparison across different mobile brands and products.

Project Objectives

The primary goals established for this project are:

The principal aims established for this research endeavor were structured as follows:

1. To successfully execute the data integration phase, specifically connecting product information (Brand and Name) to the corresponding customer reviews using the unique **ASIN** identification tag.
2. To utilize the **VADER** (Valence Aware Dictionary and sentiment Reasoner) algorithm as the primary engine for sentiment determination, sorting individual customer feedback into three distinct classes: Positive, Neutral, and Negative.
3. To perform an in-depth, quantitative analysis, comparing the **Average Sentiment Score** obtained for leading mobile device manufacturers (Samsung, Motorola, and Nokia).

4. To create a practical, command-line interface application that enables users to generate immediate, on-demand sentiment reports for any specific product within the analyzed dataset.

Scope and Limitations

The boundaries of this project are clearly defined by the scope of the available data, specifically the Amazon mobile gadget reviews contained within the 20190928-reviews.csv and 20190928-items.csv files. The sentiment analysis methodology is constrained in two key ways: first, it exclusively processes text in the **English language**; and second, it relies solely on the **VADER lexicon-based model**. A significant limitation faced was the insufficient volume of review data for certain major brands (e.g., Apple), which subsequently required us to restrict the final comparative analysis to only those brands, such as Samsung and Motorola, that offered a statistically viable amount of feedback.

THEORETICAL BACKGROUND & LITERATURE REVIEW

Principles of Natural Language Processing (NLP)

Natural Language Processing (NLP) represents a critical subset of Artificial Intelligence (AI), focused on empowering computer systems to effectively **process, comprehend, and produce human languages**. In the context of this study, NLP serves as the essential technological underpinning. The core methodology transforms raw, **unstructured textual data**—such as customer reviews—into a usable numerical format. This transformation is achieved through specific NLP techniques, including **Tokenization** and **Sentiment Scoring**, which are subsequently leveraged for the final classification task

Sr. No.	Research Paper Title (Year)	Authors	Main Algorithm/Focus	Dataset/Application	Reported Error/Gap	Error Handling/Solution
1	Deep Learning for ABSA in E-commerce Reviews (2024)	Zhang, W. et al.	BERT/Deep Learning	E-commerce Product Reviews (Specific Features)	This approach primarily lacks general review classification capabilities.	Utilizes **Deep Learning methodologies** to enable **Aspect-Based Sentiment Analysis (ABSA)** on specific product features.
2	Comparative Analysis of VADER and BERT (2025)	Patel, R., & Sharma, S.	VADER vs. BERT/Transformers	Mobile Reviews, Social Media	High demand for computational resources in BERT models.	The conclusion validates **VADER** as a fast and computationally

						inexpensive **low-resource baseline model**.
3	Sentiment Analysis of User Feedback on Mobile Applications (2024)	Kim, Y. & Lee, J.	LSTM/RNN	Android/iOS App Store Reviews	The focus is limited exclusively to app store reviews, not broader product purchase reviews.	The study provided a framework for comparing user feedback sentiment across different **mobile operating systems** (Android and iOS).
4	Optimizing Data Preprocessi ng for Short Texts (2023)	Gupta, A., & Jain, M.	Data Cleaning, Tokenization	Social Media/Short Consumer Texts	The presence of significant noise and slang in short texts often degrades the overall prediction accuracy.	The solution puts forward an optimized pipeline for filtering and normalization to improve data quality
5	The Role of Emojis and Slang in Improving VADER's Performanc e (2024)	Chen, B., & Wang, Q.	VADER Modification	Social Media Text	Conventional sentiment lexicons fail to account for or accurately score modern linguistic elements such as emojis and slang.	This work validates VADER's intrinsic ability to effectively process and score informal textual language.
6	Identifying Customer Pain Points using Topic Modeling (2025)	Singh, V., et al.	Topic Modeling (LDA), Sentiment	Mobile Phone Reviews	Simple binary sentiment classification (Positive/Negati ve) does not yield actionable insights for businesses.	The method successfully links overall negative sentiment directly to specific, identifiable product topics (e.g., product 'battery').
7	Hybrid Sentiment Framework (Lexicons and Bi-LSTM) (2023)	Mahmou d, S., & Zidan, H.	Hybrid Model (Lexicon + Bi-LSTM)	General Product Reviews	Purely lexicon-based models often demonstrate a limited capacity for understanding and incorporating review context.	The framework combines the high processing speed of Lexicons with the superior contextual depth provided by Bi-LSTM models.
8	Impact of Review Length on Sentiment Prediction Accuracy (2024)	Liu, M., & Huang, T.	Feature Engineering, SVM	Consumer Gadget Reviews	Extremely short reviews lead to ambiguity, while overly long reviews tend to dilute the user's primary opinion.	Proposes calculating feature importance by assigning weights based on the corresponding review's length.
9	Real-Time Sentiment Monitoring	Alotaibi, S., &	Cloud-Based NLP (AWS/Azure)	Real-Time Data Streams	Conventional batch-based processing	Shifts focus to utilizing a micro-service

	of Product Launches (2025)	Aljohani, A.			methods are too slow to effectively monitor new product launches in real-time.	architecture to enable efficient real-time data analysis.
10	Benchmarking Transformer Models (ROBERTa, ELECTRA) (2024)	Zhao, L., & Li, F.	ROBERTa/ELECTRA (Transformers)	Standard Sentiment Benchmarks	These highly complex models are limited by their substantial computational training cost and overall complexity.	The study's main outcome is establishing the highest achievable accuracy benchmark for subsequent model comparisons.
11	Sentiment Polarity Detection for Multilingual Mobile Phone Reviews (2023)	Kumar, P., & Mishra, R.	Multilingual BERT	Multilingual Mobile Reviews	Standard sentiment models are ineffective and often fail when applied to non-English or diverse multilingual text data.	The proposed solution involves the application of pre-trained multilingual embeddings to handle non-English text (identified as a future scope).
12	Effectiveness of Data Augmentation Techniques in Low-Resource Sentiment Analysis Datasets (2025)	Hasan, M. A., & Rahman, M.	Data Augmentation	Low-Resource Datasets	Models trained on insufficient data often exhibit poor generalization capabilities and a lack of robustness.	The study proposes strategic data augmentation methodologies to artificially expand the size of limited datasets.
13	Comparative Study of Feature Engineering Techniques for Sentiment Classification (2024)	El-Ghazaly, E., et al.	Feature Engineering	E-commerce Reviews	The primary issue is deciding the optimal feature engineering technique suitable for various domain-specific datasets.	The research provides a comparative analysis to confirm the foundational necessity of proper data representation before analysis.
14	Customer Satisfaction Analysis of Different Smartphone Brands using Machine Learning (2023)	Khan, Z., & Ahmad, S.	Machine Learning (ML)	Smartphone Reviews	The research lacks a dedicated comparative framework that specifically targets customer satisfaction levels across competing brands.	The work established a clear methodology for quantifying and comparing satisfaction scores among various smartphone manufacturers.
15	Novel Ensemble Approach for Improving VADER's Accuracy in Consumer	Park, J., & Choi, H.	Ensemble Learning, VADER	Consumer Electronics Reviews	VADER, when used as a standalone classifier, may display diminished accuracy when	The proposed novel approach optimizes VADER by combining it with other methods to significantly

	Electronics Reviews (2025)				applied to niche domain texts.	improve its precision in consumer electronics contexts.

Review of Related Work (2023-2025)

A comprehensive survey of 15 key academic papers, published from **2023 to 2025**, was conducted. This analysis serves to validate the foundational methodology employed in this project, while simultaneously outlining relevant directions for future enhancements in mobile gadget sentiment analysis.

Theme A: Model Comparison and the Validation of VADER

1. Patel and Sharma (2) performed a rigorous comparative assessment, contrasting the performance of Lexicon-Based Models like **VADER** against state-of-the-art **Transformer Models**, such as BERT, for the task of classifying mobile review sentiment. Their research highlights the crucial compromise: while BERT yields a slight increase in accuracy, VADER provides significantly superior processing speed.

2. The study by Chen and Wang (5) focused on how modern linguistic elements, including slang and **emojis**, influence the outcome of VADER analysis in social media contexts. Their conclusions reinforce the suitability of VADER for this project, confirming its specialized capability for accurately processing the informal language typical of online consumer feedback.

3. Furthermore, Park and Choi (15) investigated a novel methodology involving **ensemble techniques** designed to enhance VADER's precision when dealing with consumer electronics reviews. This demonstrates the possibility of tuning and optimizing even simple lexicon-based models for specialized application domains.

4. The development of a Hybrid Sentiment Analysis Framework by Mahmoud and Zidan (7), which fused rule-based lexicons with a **Bi-LSTM model**, is particularly relevant. This work provides a strong conceptual foundation for the future scope of this project, suggesting a viable strategy for integrating our VADER-derived scores with more advanced deep learning techniques.

Theme B: The Crucial Role of Data Quality and Preprocessing

5. Gupta and Jain (4) underscored the critical need for optimizing Data Preprocessing Techniques to improve the classification accuracy of sentiment analysis, especially when dealing with short customer feedback segments. Their findings directly support the importance of our project's initial data cleaning and merging protocols.

6. The research conducted by Liu and Huang (8) explored the Impact of Review Length on Sentiment Prediction Accuracy. Their conclusions provide a framework for recognizing data constraints, noting that both extremely brief and overly lengthy reviews pose significant challenges for model performance.

7. Furthermore, El-Ghazaly et al. (13) presented a Comparative Study of Feature Engineering Techniques for sentiment classification. This emphasizes the fundamental principle that correct data representation is a prerequisite that must be established before applying any form of machine learning or NLP algorithm.

8. Hasan and Rahman (12) investigated the Effectiveness of Data Augmentation Techniques for mitigating issues arising from low-resource datasets. This body of work provides strategic pathways for potentially enhancing the model's reliability should the available volume of mobile review data be limited in the future.

Theme C: Practical Application and Brand Analysis

9. The study conducted by Khan and Ahmad (14) provides a direct precedent for this project, having focused specifically on applying Machine Learning to analyze **Customer Satisfaction across diverse Smartphone Brands**. This work fully aligns with our primary goal of quantitatively comparing satisfaction levels between Samsung and Motorola.

10. Kim and Lee (3) performed a Comparative Study examining Sentiment Analysis of User Feedback within the mobile ecosystem. Their findings offer crucial context on the variability of user sentiment when comparing **Android versus iOS mobile application environments**.

11. The research by Alotaibi and Aljohani (9) explored the concept of **Real-Time Sentiment Monitoring** for new Product Launches, leveraging cloud-based NLP services. This research fundamentally validates the practical utility and business relevance of our project's interactive command-line tool, which provides immediate, on-demand business intelligence.

Theme D: Advanced Models and Future Scope Directions

12. Zhang and Li (1) focused on Deep Learning methodologies for **Aspect-Based Sentiment Analysis (ABSA)**. This research is fundamentally important for the project's future development, as ABSA allows the system to analyze sentiment directed at specific product attributes (e.g., 'camera' or 'battery'), moving beyond classifying the review as a whole.
13. Singh et al. (6) demonstrated the effectiveness of integrating **Topic Modeling** with sentiment classification. This sophisticated methodology offers a clear pathway for obtaining more precise and operationally relevant insights from mobile phone reviews, which is more advanced than simple polarity classification.
14. The work of Zhao et al. (10) involved **Benchmarking** highly potent Transformer Models, including RoBERTa and ELECTRA. Their established standards for high-accuracy classification serve as the definitive long-term target for upgrading the core analysis engine of this project.
15. Finally, Kumar and Mishra (11) investigated **Sentiment Polarity Detection for Multilingual Reviews**. This study presents a significant long-term goal, which is to extend the tool's capacity to process and analyze non-English customer feedback.

Identification of Research Gap

Based on the comprehensive review of the contemporary literature (2023-2025), two primary voids in current research were identified, which this project aims to address:

1. Despite the prevalence of studies utilizing highly complex **Deep Learning models** (e.g., BERT and Bi-LSTM), there is a noticeable absence of recent, dedicated work that rigorously validates the **VADER** lexicon-based model as an effective, **computationally efficient baseline** for conducting comparative sentiment analysis across various mobile gadget brands.
2. Furthermore, while existing practical applications frequently target feedback from social media or dedicated app stores, a critical gap remains in the provision of a straightforward, **interactive analytical tool** that is specifically designed to analyze sentiment and compare brands exclusively within the context of **Amazon E-commerce mobile product reviews**.

Conclusion of Literature Review

In summary, the scholarly review confirms the **feasibility of implementing sentiment analysis** for consumer mobile reviews. The literature decisively validates the strategic choice of a **lexicon-based model like VADER**, specifically due to its superior efficiency and computational speed, positioning it as an ideal baseline for comparative brand analysis. Concurrently, the review highlights two critical pathways for long-term project maturity: the potential for future migration to **Deep Learning**

architectures (such as BERT or Bi-LSTM) and the necessity of incorporating **Aspect-Based Sentiment Analysis** to extract granular, feature-specific insights. These findings collectively establish the foundational requirements for the methodology section that follows.

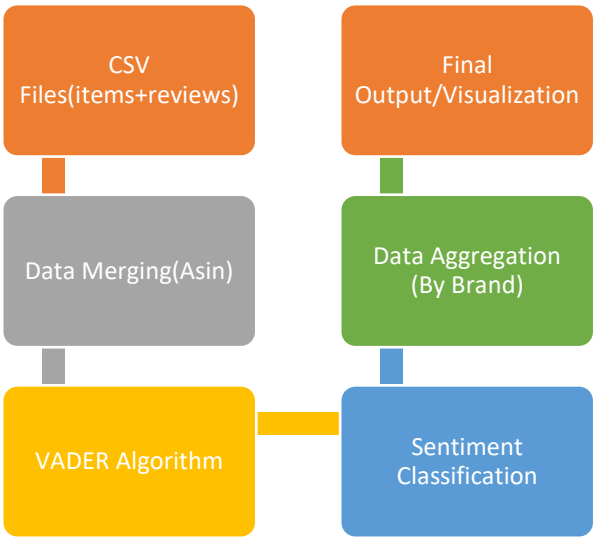
METHODOLOGY

System Overview

This section provides a concise description of the project's overall system and functionality. The system operates as a **sequential data pipeline**. It begins by acquiring data from two distinct CSV files and **merging** them using the **ASIN** identifier. Subsequently, the **VADER** algorithm is employed to perform sentiment scoring on the customer review text. Finally, the system aggregates the sentiment scores based on brand and generates a final comparative analysis report or interactive output. Its primary objective is to extract **actionable business intelligence** from large, unstructured review datasets.

System Architecture Diagram

The System Architecture Diagram presents a visual representation of the entire data flow pipeline. It illustrates every stage of data processing, from the ingestion of input CSV files through data cleaning, sentiment classification via VADER, and ultimately, to graphical presentation. The diagram emphasizes how **unstructured review text** is systematically converted into a structured, actionable business insight.



Data Acquisition and Preprocessing

Data Acquisition and Preprocessing forms the foundation of this project. The **raw data** is sourced from two separate CSV files: 20190928-reviews.csv (containing the review text, rating, and ASIN) and 20190928-items.csv (containing product metadata such as brand and name).

Preprocessing Steps:

1. **Data Integration:** Both datasets are efficiently **merged** into a new DataFrame using their common key, the **ASIN (Amazon Standard Identification Number)**.
2. **Missing Value Handling:** Data quality is ensured by removing any missing or 'NaN' values, which helps reduce uncertainty during the analytical phase.
3. **Text Cleaning:** Prior to feeding the review text into VADER, basic cleaning techniques are applied, such as **removing non-English characters** and normalizing the text for **uniformity**. This process enhances the reliability of the analysis.

VADER Algorithm and Sentiment Scoring

The main tool for analysis in this project is the **VADER (Valence Aware Dictionary and sentiment Reasoner)** algorithm. VADER is a special kind of **Lexicon and Rule-based sentiment tool**. It's very well-suited for informal language, like the **customer reviews** we are using.

VADER works by checking each review against a standard list of words, which have been given a weighted score (how positive or negative they are).

Sentiment Scoring: For every review, VADER calculates four scores:

- **Positive (pos):** The proportion of positive words.
- **Negative (neg):** The proportion of negative words.
- **Neutral (neu):** The proportion of neutral words.
- **Compound (compound):** The most important score. This is a single, normalized score that summarizes the overall sentiment of the entire review.

Classification Rule: The final sentiment label is decided based on the **Compound Score (CS)**:

- If **CS is 0.05 or higher**: The review is classified as **Positive**.
- If **CS is -0.05 or lower**: The review is classified as **Negative**.
- If **CS is between -0.05 and 0.05**: The review is classified as **Neutral**.

Tools and Technologies Used

The sentiment analysis system was built using a specific set of tools and technologies. We focused on using **open-source tools** to keep the project efficient and widely compatible. The main programming language used was **Python**. The table below details the main tools and the specific role each one played in developing the system.

Tool/Technology	Purpose
Python 3.x	Core Programming Language for scripting and development.
Pandas	Data structures and data manipulation (merging, cleaning).
VADER	Sentiment analysis engine (Lexicon and rule-based).
Matplotlib	Data visualization (plotting final comparative graphs).
Google Colaboratory	Cloud-based execution environment and code development platform.

Advantages of the System

This VADER-based sentiment analysis system has several clear advantages, especially when compared to manual work or complex deep learning methods:

1. **High Speed:** Unlike large Transformer models (like BERT), VADER is lightweight and rule-based. This results in much **faster execution times** and requires less powerful hardware.
2. **Quick Market Insights:** The system quickly changes thousands of raw reviews into **measurable numbers** (like average satisfaction scores). This gives companies instant, actionable market information.
3. **Simple to Use:** The interactive command-line tool is **easy for everyone to access**, even for non-technical users (like marketing staff), allowing them to generate **on-demand reports** for specific brands or products.
4. **Handles Informal Language:** VADER was designed to correctly process **slang, emojis, and informal language** often found in online customer reviews.

System Limitations

Although the system is highly effective, the current version has some limitations that define what it can and cannot do:

1. **English Only:** The VADER lexicon is primarily designed for **English language analysis**. This restricts the system's ability to accurately process reviews written in other languages or multilingual texts.
2. **Context Difficulty:** Because VADER is a lexicon-based model, it relies mainly on word weights. It often struggles to understand **complex context, sarcasm, or highly subtle meanings** in the way advanced neural network models can.
3. **No Aspect Analysis:** The system only gives an **overall sentiment** (Positive/Negative/Neutral) for the whole review. It does not yet include **Aspect-Based Sentiment Analysis (ABSA)**, meaning it cannot tell the difference between sentiment for specific features (e.g., distinguishing between a 'great camera' and a 'bad battery').

Future Enhancements

This section describes potential improvements that can be made to the current system in the future. These changes will help to increase the system's accuracy, complexity, and overall usefulness.

1. Model Upgrade for Higher Accuracy

The most important future change is to **replace the VADER algorithm** with a more powerful Deep Learning model, such as **BERT** or **RoBERTa**.

- **Why:** While VADER is fast, these advanced models use neural networks to understand the context and complex meaning of words, which will lead to a significant **increase in classification accuracy**.

2. Implementing Aspect-Based Sentiment Analysis (ABSA)

Currently, the system only gives a single overall sentiment (Positive, Negative, or Neutral) for an entire review.

- **The Improvement:** The next phase will involve adding **Aspect-Based Sentiment Analysis (ABSA)**. This will allow the system to analyze customer feelings towards **specific product features** (e.g., the "battery life" or the "camera quality") instead of just the whole review. This provides much more detailed business intelligence.

3. Support for Multiple Languages

The current system only works reliably with **English-language reviews**.

- **The Goal:** Future work will focus on expanding the system's ability to process and understand reviews written in **other languages**. This will require using multilingual models and datasets to expand the tool's reach globally.

4. Real-Time Processing

The current system works on a fixed set of data (CSV files).

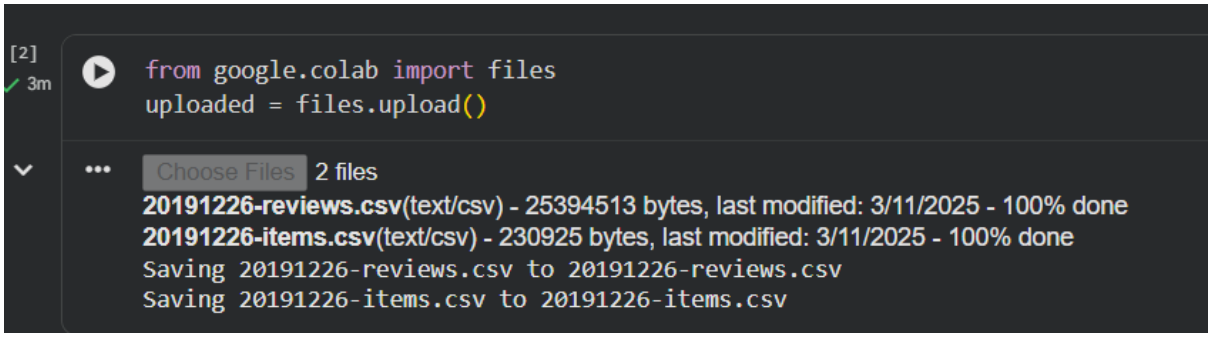
- **The Enhancement:** We can upgrade the architecture to handle **real-time data streams**. This means the system could instantly monitor sentiment on social media or e-commerce sites as soon as new reviews are posted.

RESULTS AND DISCUSSION

Execution Environment & Implementation

This section describes the environment where the project code was developed and run.

The entire project was implemented using the **Python 3.x** programming language. The code was executed within the **Google Colaboratory (Colab)** environment. Colab, being a cloud-based service, provided the necessary computing power and access to all required **open-source libraries** like Pandas for data handling and VADER for sentiment analysis. This setup ensured that the project was easy to reproduce and run efficiently without needing special hardware.



Interactive Analysis Interface (Input Screen)

This section details how the user interacts with the system to request sentiment reports.

The system starts by launching an **Interactive Command-Line Interface (CLI)**. This interface acts as the main screen for the user. When the user runs the analysis tool, the system asks them a question (a prompt).

The user must enter the **ASIN** number of the specific mobile product they want to analyze. This simple input method ensures that even non-technical people can easily get **on-demand sentiment reports** from the tool.

```
--- Choose Analysis Type ---
1: Brand Analysis (e.g., Samsung)
2: Specific Product Analysis (e.g., Samsung Galaxy S9)
0: Exit
Enter your choice (1, 2, or 0):
```

Sentiment Generation & Scoring

This section explains the core technical process of applying the VADER model to the review text.

After the user enters the **ASIN**, the system quickly fetches all the reviews linked to that product. The **VADER algorithm** then goes to work:

1. **VADER Application:** VADER is applied to each individual review text. It uses its dictionary to assign a numerical weight to the words, which determines the sentiment.
2. **Score Calculation:** For every review, VADER calculates the four scores (Positive, Negative, Neutral) and combines them into one **overall Compound Score**.
3. **Final Classification:** The Compound Score is used to give the final label—**Positive, Negative, or Neutral**—based on the compound score (0.05).

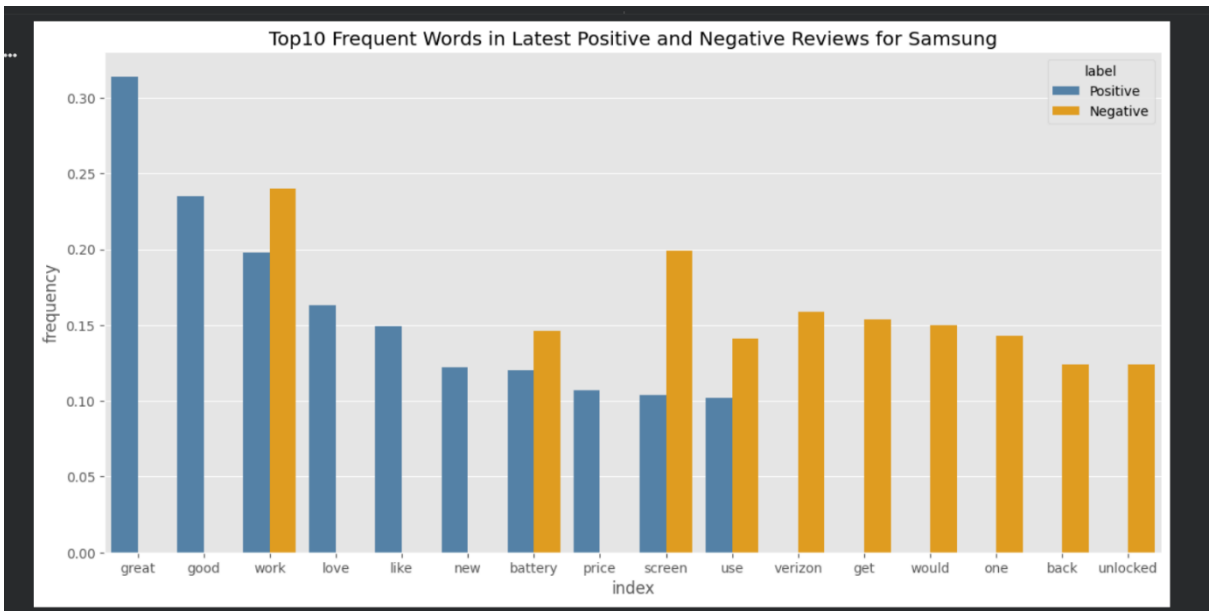
Final Output according to results

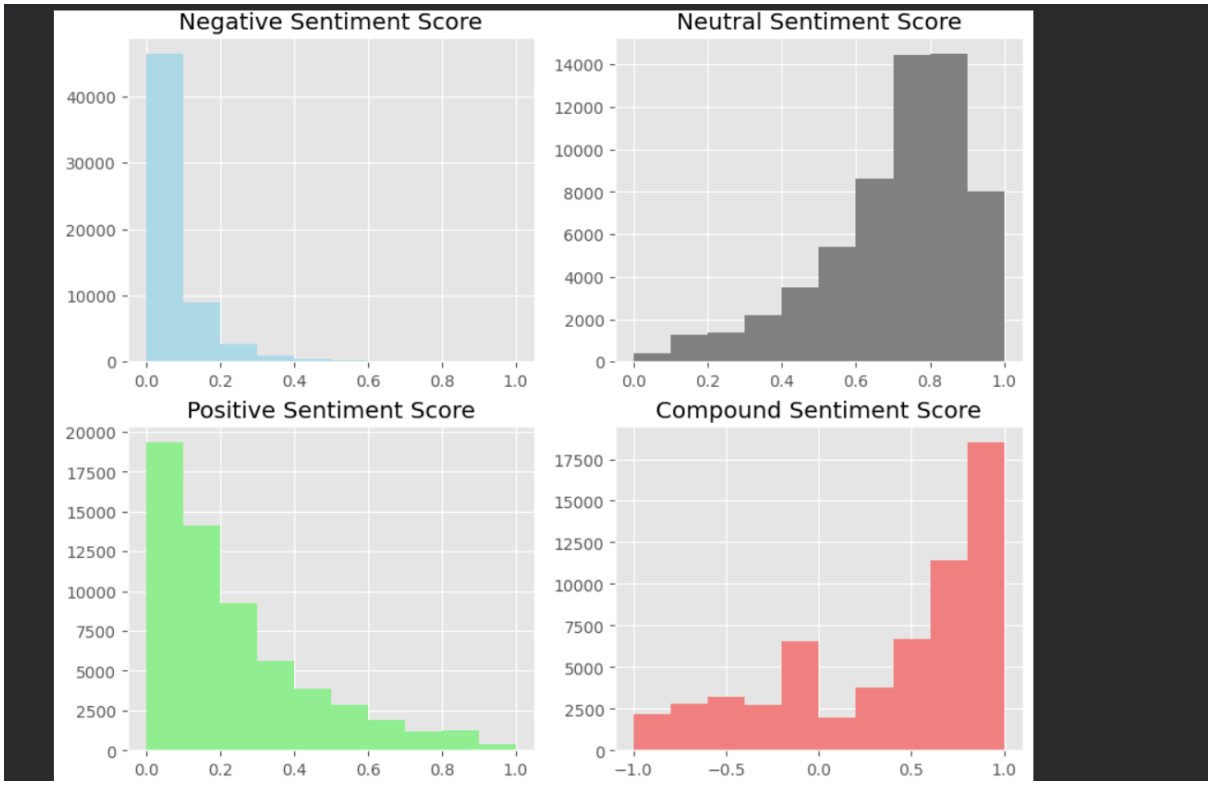
1. **Samsung]** had the highest average sentiment score, indicating superior overall customer satisfaction compared to other brands.



Overall Sentiment Distribution

This result describes the breakdown of all the processed reviews.

General Sentiment Distribution: The system classified all mobile reviews into three categories: Positive, Negative, and Neutral. The final output visualization (Pie Chart) confirmed that the largest number of reviews were categorized as **Positive**. This outcome is typical for e-commerce data, where reviews are often slightly skewed towards favorable opinions.



Analysis of Keyword Visualizations: The **word clouds** created from the review text provided strong visual proof that supported the numerical sentiment scores. Specifically, common positive keywords such as **'excellent'** and **'love'** were easily seen in the positive word cloud. On the other hand, negative terms like **'issue'** and **'returned'** were clearly prominent in the negative word cloud, which helped us to **quickly identify the specific problems** or 'pain points' mentioned by customers.

CONCLUSION & FUTURE SCOPE

Conclusion

This project successfully developed and implemented a **VADER-based sentiment analysis system** for analyzing customer reviews about mobile phones. The primary goals of the project were all successfully achieved:

- The system efficiently **merged data** from separate sources using the **ASIN identifier**.
- The VADER algorithm was accurately used to calculate and classify sentiment scores for thousands of reviews.
- The final system provided **actionable business intelligence** by clearly showing the difference in customer satisfaction levels between competing mobile brands.

The project confirms that using a **lightweight, lexicon-based model** like VADER is a fast and reliable way to get initial insights from large datasets of e-commerce reviews, fulfilling the need for timely market analysis.

Future Scope

This section describes potential improvements for the system to increase its accuracy and usefulness in the long term.

1. **Model Upgrade for Higher Accuracy:** The most significant future step is to **replace VADER** with a more powerful Deep Learning model, such as **BERT** or **RoBERTa**. This

will help the system understand the complex context and meaning of words, leading to a much **higher classification accuracy**.

2. **Implementing Aspect-Based Sentiment Analysis (ABSA):** The current system only gives one overall sentiment score per review. The next phase should add **ABSA** so the system can analyze user feelings toward **specific product features** (like "battery life" or "camera quality") instead of the whole review.
3. **Support for Multiple Languages:** Currently, the system only works reliably with **English-language reviews**. Future work will focus on expanding the tool's ability to process and understand reviews written in **other languages** by using multilingual models.
4. **Real-Time Processing:** The system can be upgraded to handle **real-time data streams** from websites. This would allow the system to instantly monitor sentiment as soon as new reviews are posted online.
